

Mutual Exclusions Insertion Formalisation

Quentin Nivon, Gwen Salaün

September 16, 2025

Based on the definitions of mutual exclusions presented in the paper, one can now add to G the mutually exclusive tasks not already belonging to it. The tasks not already belonging to G are $\bar{V} = \bigcup_{T \in S_T} \{v \in \mathbf{tasks}(T) \mid v \notin G\}$. To perform the insertion, we must consider the set of mutually exclusive tasks of each task $t \in \bar{V}$, that is M_t . Let us then consider two possible cases: either (i) the set only contains tasks that do not belong to G , i.e., $M_t \cap V = \emptyset$, or (ii) the set contains at least one task belonging to G , i.e., $M_t \cap V \neq \emptyset$.

For case (i), the solution is rather simple: t and each task of M_t are added to the graph, without any connection, as initial nodes. By doing so, \mathcal{P}_G^0 now contains $|M_t| + 1$ new paths, containing each a single task of M_t , or t . By construction, there is no path of G containing both t and a task of M_t . Thus, they are mutually exclusive, as desired.

For case (ii), the solution is slightly more complex. Let us break M_t into two sets: the set of tasks already belonging to G called \tilde{M}_t , and the set of tasks not belonging to G called \bar{M}_t . We have that $\tilde{M}_t \cup \bar{M}_t = M_t$. A simple—yet naive—way of inserting t and the tasks belonging to \bar{M}_t into G would be to do just as in case (i), that is, adding them to G without any connection, as initial nodes. However, unlike in case (i), t is, by definition, constrained with regards to some tasks of the graph (the \tilde{M}_t). Consequently, inserting these tasks as performed in case (i) would create many unspecified mutual exclusions. To avoid this, the proposed method consists in connecting t and the tasks belonging to \bar{M}_t to a particular node of G while preserving the existing mutual exclusions and limiting the number of unspecified mutual exclusions. This particular node is one of the *closest inevitable common ancestors* of the tasks belonging to \tilde{M}_t , and of the mutually exclusive tasks of the tasks of \bar{M}_t already belonging to G .

Definition 1 (Closest Inevitable Common Ancestors). *Let $G = (V, E, \Sigma)$ be a BPMN process. $\forall v_1, \dots, v_n \in V$, the closest inevitable common ancestors of (v_1, \dots, v_n) are all the nodes $v_C \in V$ such that:*

- $\forall i \in [1..n], \forall \hat{p} \in \hat{\mathcal{P}}_G^0, v_i \in \hat{p} \Rightarrow (v_C \in \hat{p} \wedge \mathbf{index}(v_C) < \mathbf{index}(v_i))$ (*inevitability, commonality, ancestry*);
- $\forall p_{v_C} = (v_C, v_b, \dots, v_m) \in \mathcal{P}_G(v_C), \nexists j \in [b..m]$ such that v_j is a common ancestor of (v_1, \dots, v_n) (*closeness*).

Among the eventual multiple closest inevitable common ancestors, one of them is selected, and t and the tasks belonging to \bar{M}_t are inserted to G as children of this ancestor. As desired, task t is now mutually exclusive of the tasks of M_t .

Proposition 1 (Validity of the Closest Inevitable Common Ancestors). *Let $G = (V, E, \Sigma)$ be a BPMN process, let M_t be the set of mutually exclusive tasks of a task $t \in V^1$, let $\tilde{M}_t = M_t \cap V$, let $\bar{M}_t = M_t \setminus \tilde{M}_t$, and let V_C be the set of closest inevitable common ancestors of the tasks belonging to $\tilde{M}_t \cup \bigcup_{\substack{\bar{t} \in \bar{M}_t \\ m \in \mathbf{mutex}(\bar{t}) \\ m \in G}}$. We state that inserting t and the tasks \bar{M}_t into G as children of any*

¹One could take $t \notin V$ without changing the validity of the statement.

$v_C \in V_C$ make t weakly mutually exclusive of the tasks M_t .

Proof. Let $G = (V, E, \Sigma)$ be a BPMN process, let M_t be the set of mutually exclusive tasks of a task $t \in V^2$, let $\tilde{M}_t = M_t \cap V$, let $\overline{M}_t = M_t \setminus \tilde{M}_t$, and let V_C be the set of closest inevitable common ancestors of the tasks belonging to $\tilde{M}_t \cup \bigcup_{\substack{\bar{t} \in \overline{M}_t \\ m \in G}} \bigcup_{m \in \text{mutex}(\bar{t})}$. We will show that, $\forall v_C \in V_C$,

adding t and the tasks of \overline{M}_t as children of v_C make t weakly mutually exclusive of the tasks belonging to M_t .

Adding t and the tasks \overline{M}_t as children of v_C creates a BPMN process $G' = (V', E', \Sigma')$, where:

- $V' = V \cup \overline{M}_t \cup \{t\}$;
- $E' = E \cup \bigcup_{\bar{t} \in \overline{M}_t} \{v_C \rightarrow \bar{t}\} \cup \{v_C \rightarrow t\}$;
- $\Sigma' = \Sigma \cup \bigcup_{\bar{t} \in \overline{M}_t} \{\sigma(\bar{t})\} \cup \{\sigma(t)\}$.

Consequently, we have that

$$\hat{\mathcal{P}}_{G'}^0 = \hat{\mathcal{P}}_G^0 \cup \bigcup_{\bar{t} \in \overline{M}_t} \bigcup_{p \in \hat{\mathcal{P}}_G^0} \{(p[:v_C], \bar{t}) \mid v_C \in p\} \cup \bigcup_{p \in \hat{\mathcal{P}}_G^0} \{(p[:v_C], t) \mid v_C \in p\}$$

By construction, there is no $p \in \hat{\mathcal{P}}_{G'}^0$ containing both t and a task $\bar{t} \in \overline{M}_t$. Moreover, by definition of v_C , we have that $\forall \tilde{t} \in \tilde{M}_t$, $\forall p \in \hat{\mathcal{P}}_{G'}^0$, $\tilde{t} \in p \Rightarrow p = (v_1, \dots, v_C, \dots, \tilde{t}, \dots, v_z)$. Thus, by construction of G' , there is no $p \in \hat{\mathcal{P}}_{G'}^0$ containing both t and a task $\tilde{t} \in \tilde{M}_t$. Consequently, t is weakly mutually exclusive of all $\tilde{t} \in \tilde{M}_t$, and of all $\bar{t} \in \overline{M}_t$, which corresponds to all the tasks of M_t . \square

Remark 1. *It is worth mentioning that considering the closest inevitable common ancestor of (the barbarian expression) $\tilde{M}_t \cup \bigcup_{\bar{t} \in \overline{M}_t} \bigcup_{m \in \text{mutex}(\bar{t})} m$ is mandatory in order to preserve the original mutual*

exclusions. Indeed, adding the tasks of \overline{M}_t as children of the closest inevitable common ancestor of \tilde{M}_t only could potentially prevent a task $\bar{t} \in \overline{M}_t$ from being mutually exclusive of one of its mutually exclusive tasks, in the case where such a task is a predecessor of the closest inevitable common ancestor of \tilde{M}_t .

²One could take $t \notin V$ without changing the validity of the statement.
